(54) **GLASS TUBE ELEMENT WITH IMPROVED QUALITY**

(57) The present invention relates to a glass tube element having an improved quality that is preferably made such that cooling of the hot tube is achieved through cooling rolls or castors .

Fig. 3

Description

[0001] The present invention relates to a glass tube element.

5 Background of the invention

[0002] Glass tube elements are widely used as basic parts in many different industries. One reason for that is that glass tube elements have the advantage that they can at least in part be reshaped in a subsequent processing chain easily and with convenient means in many different ways. A plurality of different products can be produced from just a few different glass tube elements as basic parts. This allows a flexible and wide product range at manageable costs and with widely available technical means.

[0003] Especially in the field of pharmaceutical containers glass tube elements are of particular interest as basic parts for vials, syringes or the like. Furthermore, glass can be made such that it is free of toxic ingredients like Pb, As, and Cd, has high chemical stability and also high chemical inertness. Because of the high chemical stability of the glass the precipitation or leaking out of substances of the glass wall (or shell) of the glass tube element can be eliminated or at least reduced, which particularly indicates great suitability for the pharmaceutical domain.

[0004] Along with the high degree of freedom concerning design options, it is apparent that glass tube elements come along with advantageous properties for being used as basic parts for pharmaceutical containers in combination with pharmaceutical compositions.

[0005] However, the demands placed on pharmaceutical containers are high. And so are the demands placed on glass tube elements. For fulfilling respective specifications, it is especially required that also the respective basic parts have a uniform design, hence, geometric parameters within strict boundaries. This way it can be ensured that a product such as a syringe made on basis of a glass tube element is free of unintended tensions per se and has no mismatches with respect to other parts such as caps or the like to which it should be connected later. This allows a safe interaction of the product with other parts and a safe handling of the product in general.

[0006] Otherwise, critical situations either in the production process or during use may arise. A destruction of the product, e.g. a pharmaceutical container, might happen. Thus, the loss of the pharmaceutical composition held by the container and, in addition, risks for persons handling with the pharmaceutical container might be the result.

[0007] Therefore, quality requirements placed on pharmaceutical container are likewise also placed on the basic parts in form of glass tube elements. So far, there have been identified a large variety of geometric parameters of the glass tube elements which can be made subject to optimization in order to achieve glass tube elements of high quality.

[0008] However, the demands on the quality are continuously increasing. It is, therefore, necessary to improve further the quality of the pharmaceutical containers, hence, the quality of the glass tube elements.

[0009] It is, thus, the object of the present invention to provide glass tube elements of improved quality, which are particularly suitable for use as basic parts for further processing such as reshaping according to the needs in the pharmaceutical industry. It is also an object of the present invention to provide a use for such a glass tube element and a method for producing such a glass tube element.

40 Description of the invention

[0010] The problem is solved by the invention according to a first aspect in that a glass tube element comprising at least one section which is of hollow cylindrical form, wherein the section has at least one shell which encloses at least one lumen;

wherein when conducting optical measurements on the glass tube element by means of at least one light ray which extends along a measurement path, which measurement path extends in a direction of measurement perpendicular to the direction of the main extension of the glass tube element and which measurement path is tangent to the surface of the shell facing away from the lumen and which measurement path touches the surface for different measurements at different positions each having a different azimuth angle within a cylindrical coordinate system fixedly attached to the glass tube element and having its origin on the center axis of the glass tube element, the optical delays of the light ray obtained from the different measurements have values which all fall within a range having a size of between 3 and 30 nm is proposed.

[0011] The invention is, thus, based on the surprising finding that glass tube elements have improved quality and, thus, are particularly suitable for subsequent processing such as at least partly reshaping if the stress distribution on and/or beneath the surface is arranged such that the optical delay is homogeneous along a path extending on the surface, such as around the complete circumference, of the glass tube element. Such a homogeneous or uniform distribution has been found to indicate a glass tube element of particular high quality. The inventors found that the optical delay is homogeneous if the variation is limited within a certain range. It is the astonishing finding that the lower border of the range is larger than zero and the upper border is located at about ten times the lower border.

[0012] It is astonishing that an increased homogeneity of the optical delay in turn results in improved quality of the glass tube element. As one result the inventors found that improved quality comes along with improved geometric parameters such as the straightness of the glass tube element. It is evident that an improved straightness enables an improved usability for subsequent manufacturing steps as well as improved usability of the glass tube elements in combination with other elements. This is because for example the interconnectability is improved. The increased homogeneity of the optical delay also allows to divide the glass tube elements in subelements in a more reliable and safe manner.

[0013] The inventive concept allows a surprisingly reliable and cheap way to obtain a glass tube element of high quality, hence, high quality products based on such glass tube elements.

[0014] In preferred embodiments the stress is mechanical stress. It is acknowledged that the terms "shell (of the cylinder/glass tube element)" and "wall (of the cylinder/glass tube element)" are used as synonyms here.

[0015] It is acknowledged that the terms "outer surface (of the shell)" and "surface (of the shell) facing away from the lumen" are used as synonyms here.

[0016] It is acknowledged that preferably certain values all fall within a range having a size of between X and Y, if the difference value between every two of the certain values is between (and inclusive of) X and Y. In other words, a common offset of the values of the measured optical delays is here not of interest.

[0017] However, in one embodiment alternatively or in addition the optical delay measured might have a value of between 10 nm and 150 nm for a shell of thickness 1 mm and where the thickness of the specimen which the light ray crosses during the optical measurements is also 1 mm.

[0018] It is acknowledged that even if the measurement path is tangent to the surface of the shell facing away from the lumen, the person skilled in the art understands that conducting optical measurements in reality always will include also one or more light rays which are shifted towards the center axis of the glass tube element and/or which have some spatial extension in a direction perpendicular to the direction of propagation, i.e. they propagate at least partly within the shell. For example a tangential light ray might preferably be up to 10 μm beneath the outer surface.

[0019] For example, for the optical measurements, the light ray has a linear polarization which encloses an angle of 45 degrees with the center axis of the glass tube element. For example, the light ray has light of wavelength 630 nm, 633 nm or 635 nm. For example the ambient temperature is room temperature.

[0020] In one embodiment it might alternatively or in addition be preferred that the light ray comprises a wavelength of between 250 and 900 nm, preferably between 390 and 800 nm, most preferably 394 nm or 633 nm.

[0021] In one embodiment it might alternatively or in addition be preferred that the glass tube element is surrounded by at least one fluid such that at least the surface of the shell facing away from the lumen is in contact with the fluid.

[0022] In one embodiment it might alternatively or in addition be preferred that the glass tube element is completely immersed in the at least one fluid such that at least the surface of the shell facing away from the lumen and the surface of the shell facing towards the lumen, both, are in contact with the fluid.

[0023] If the glass tube element is completely immersed in water the measurements can be performed more stable. In one embodiment it might alternatively or in addition be preferred that the fluid has, preferably for the wavelength of the light ray, an optical density which is at most 1% different compared to the optical density of the glass material of the glass tube element.

[0024] If an appropriate fluid is chosen, especially a fluid which has for the wavelength used for the measurements an optical density which is close to the optical density of the glass material of the glass tube, more reliable measurement results can be obtained.

[0025] In one embodiment it might alternatively or in addition be preferred that the fluid has, preferably for the wavelength of the light ray, an optical density of between 1.2 and 2.5, preferably between 1.3 and 1.7 and most preferably 1.362, 1.460, 1.463, 1.472, 1.473, 1.474, 1.486, between 1.492 and 1.493, 1.497, 1.501, 1.516, 1.525 or between 1.43 and 1.61.

[0026] In one embodiment it might alternatively or in addition be preferred that the fluid comprises ethyl alcohol, olive oil, carbon tetrachloride, sunflower oil, terpentine, glycerine, furfuryl alcohol, dibutylphthalat 84-74-2, toluol, benzene, dimethylphthalate, monochlorobenzene or silicon oil or any combination thereof.

[0027] In one embodiment it might alternatively or in addition be preferred that the optical delays of the light ray obtained from the different measurements have values which all fall within a range of between 10 and 150 nm, preferably between 20 and 100 nm, and/or wherein the optical delays of the light ray obtained from the different measurements have values which all fall within a range having a size of between 4 and 25 nm, preferably between 5 and 20 nm.

[0028] In one embodiment it might alternatively or in addition be preferred that 360 measurements are carried out each having a different azimuth angle selected from the integer values between, and inclusive of, zero and 359 degrees.

[0029] In one embodiment it might alternatively or in addition be preferred that each measurement is carried out for positions having the same height and/or the same radius within the cylindrical coordinate system.

[0030] In one embodiment it might alternatively or in addition be preferred that the glass tube element has a length of between 0.5 and 5 m, preferably of between 0.7 and 3 m, more preferably of between 1 and 2 m, even more preferably between 1.2 and 1.8 m and most preferably of 1.5 m.

[0031] A glass tube element which has a length in the preferred range has an improved quality. This is because a

more stable and more defined glass tube element is obtained.

[0032] In one embodiment it might alternatively or in addition be preferred that the maximal outer diameter is between 1 and 100 mm, preferably between 3 and 60 mm, more preferably of between 6 and 45 mm, 8 and 19 mm, 6 and 50 mm or 8 and 30 mm.

[0033] A glass tube element which has a maximal outer diameter in the preferred range has an improved quality. This is because a more stable and more defined glass tube element is obtained.

[0034] In one embodiment it might alternatively or in addition be preferred that the shell has an average thickness of between 0.1 and 5 mm, preferably between 0.2 and 3 mm, more preferably of between 0.3 and 2.5 mm, most preferably between 0.4 and 1.8 mm.

[0035] A glass tube element which has a preferred average thickness of the shell is particularly suitable for applying the inventive approach because an even more reliable first and second ratio can be obtained for such glass tube elements.

[0036] The term "average thickness" means here the average thickness of the shell across the length of the glass tube element. If the thickness of the shell has everywhere a constant value, the average thickness is identical to the actual thickness.

[0037] In one embodiment it might alternatively or in addition be preferred that the glass tube element comprises at least in part silicate glass, such as soda line and/or aluminosilicate glass, and/or borosilicate glass.

[0038] In one embodiment it might alternatively or in addition be preferred that the glass tube element, especially its glass material, has a transition temperature which is higher than 300 degrees C, preferably higher than 500 degrees C, more preferably higher than 520 degrees C, even more preferably higher than 530 degrees C, even more preferably higher than 550 degrees C, and most preferably higher than 600 degrees C and/or lower than 900 degrees C, preferably lower than 800 degrees C, more preferably lower than 700 degrees C, even more preferably lower than 650 degrees C, and most preferably lower than 630 degrees C.

[0039] Preferably the transition temperature refers to the transition temperature of the glass used for the wall of the glass tube element.

[0040] In one embodiment it might alternatively or in addition be preferred that the glass tube element, preferably during its production process, is at least temporarily connected to one or more further glass tube elements, preferably in one piece, and/or is part of at least one glass tube line.

[0041] It is more economic to manufacture a longer or even an endless glass tube line with subsequent confectioning of individual glass tube elements from that line with a desired length.

[0042] In one embodiment it might alternatively or in addition be preferred that the glass tube element has an average linear coefficient of thermal expansion measured in the range of 20 degrees C to 300 degrees C (CTE) between 3.0 and $10.0 \cdot 10^{-6} \text{ K}^{-1}$, preferably between 3.3 and $7.5 \cdot 10^{-6} \text{ K}^{-1}$, more preferably between 4.7 and $6.0 \cdot 10^{-6} \text{ K}^{-1}$.

[0043] It is beneficial for the glass tube to have a lower CTE, which leads to a more uniform product. Hence, in preferred embodiments, the CTE is limited to no more than $6.9 \cdot 10^{-6} \text{ K}^{-1}$ or no more than $5.9 \cdot 10^{-6} \text{ K}^{-1}$. The CTE may be measured according to DIN ISO 7991:1987.

[0044] In one embodiment it might alternatively or in addition be preferred that the glass tube element, preferably during its production process, at least during at least one part of its period of cooling passes with a defined speed of movement along a defined path of movement, preferably the path of movement extends parallel to the direction of the main extension of the glass tube element and/or in a horizontal direction, through at least one cooling device, for setting up a locally modified cooling rate of the glass tube element.

[0045] It has been surprisingly found that the geometric parameters, hence, each of the first and second ratio and the overall quality of the glass tube element can be improved, if the glass tube element undergoes a special treatment during its period of cooling. It has been proven to lead to advantageous results if the process of cooling is influenced by changing the cooling rate of the glass tube element locally.

[0046] Preferably the cooling rate of the outer surface of the glass tube element is modified. However also modifications to the cooling rate elsewhere such as within the shell of the glass tube element might be applied.

[0047] If the speed of movement and the path of movement is defined, a higher control of the cooling process can be obtained. Particularly a path of movement which is straight or at least nearly straight has been found as being preferred for a uniform and reproducible interaction.

[0048] The inventors assume that applying the mentioned treatment using the cooling device as well as the other settings, respectively, during the cooling process lead to a manipulation of the structure, especially the structure on, beneath and/or near the outer surface, of the glass tube element which in turn lead to improved geometric properties of the same.

[0049] In one embodiment it might alternatively or in addition be preferred that the speed of movement is between 1 and 1000 cm/s, preferably between 20 and 800 cm/s, more preferably between 30 and 500 cm/s and most preferably 100 cm/s.

[0050] For preferred speeds an optimal interaction time between the cooling device and the glass tube element is obtained. Hence, a glass tube element of improved quality is obtained as well.

[0051] In one embodiment it might alternatively or in addition be preferred that the glass tube element has at least temporarily a surface temperature of between T_g-50 and T_g+150 degrees C while passing through and/or along the cooling device.

[0052] The inventors have found that a glass tube element which has a surface temperature (especially the temperature of the outer surface of the shell) which is within a certain interval around the transition temperature of the material (i.e. glass) of the glass tube element, a particular beneficial interaction between the cooling device and the glass tube element can be obtained. The result is a glass tube element of improved quality.

[0053] The inventors assume that for a temperature range around the transition temperature, the glass tube element can be affected by the inventive concept in an advantageous manner compared to other temperatures because the cooling device can so to say "imprint" a modification which lead to improved properties of the glass tube element.

[0054] In preferred embodiments the surface temperature is the temperature at the outer surface.

[0055] It is acknowledged that the glass tube element has a surface temperature within the preferred temperature interval at least temporarily while passing through/along the cooling device. In other words, it is required in the preferred embodiments that the surface temperature of the glass tube element is at least for some time within the preferred temperature interval while passing through/along the cooling device.

[0056] This does not exclude that the surface temperature is, e.g. at the beginning of passing through/along the cooling device, above the upper limit and/or that the surface temperature is, e.g. at the end of passing through/along the cooling device, below the lower limit.

[0057] In one embodiment it might alternatively or in addition be preferred that the cooling device has at least one contacting device, wherein the contacting device has at least from time to time and/or area by area, preferably direct, contact with at least one area of the outer surface of the glass tube element.

[0058] It is the astonish finding that providing a contacting device allows controlling the locally existing cooling rate on the surface, respectively of the outer surface, of the glass tube element in a precise, reliable and comfortable manner. It is also possible to control the instance of time when it contacts the glass tube element. This might be controlled for example by a respective spatial placement of the contacting device within the cooling device, such that the glass tube element passes at an earlier or later instant of time along the respective contacting device. Of course, preferably not the entire contacting device must be in contact with the glass tube element, but it may. Also a part thereof might be sufficient. Of course, not the entire outer surface of the glass tube element must have contact with the contacting device, but it may. Also an area of the outer surface of the glass tube element might be sufficient.

[0059] These design parameters allow to efficiently control the degree of interaction between the contacting device and the glass tube element. The earlier, the longer and the more widely the contact between the contacting device and the glass tube element is, the more interaction between both might take place, hence, the more cooling might take place.

[0060] In further preferred embodiments the cooling device has alternatively or in addition at least one fluid dispenser device which is designed to provide a fluid, such as water, fog and/or air, preferably compressed air, preferably at least from time to time and/or area by area, on at least one area of the outer surface of the glass tube element.

[0061] Using a fluid allows an improved control of the cooling process of the glass tube element. Especially a high change of the temperature within short time can be achieved that way. This might also be used for supporting the cooling process carried out by the contacting device.

[0062] Preferably the fluid dispenser is designed at least in part in form of at least one ring nozzle. This allows that a homogeneous (and circumferential) interaction between the fluid and the glass tube element is achieved. In other words, using ring nozzles allows to cover the complete outer surface of the glass tube element. It has been proven that this lead to an improved straightness of the glass tube element at least in sections.

[0063] In also preferred embodiments the fluid dispenser is used as part of at least one air bearing and/or in combination with at least one contacting device. This allows to obtain an interaction with reduced or even without directly contacting the glass tube element with the contacting device. This may reduce contamination effects.

[0064] In one embodiment it might alternatively or in addition be preferred that the cooling device has a plurality of contacting devices, wherein preferably a first number of the plurality of contacting devices comes in contact with the outer surface of the glass tube element one after another in time and/or at different areas of the outer surface and/or a second number of the plurality of contacting devices comes in contact with the outer surface of the glass tube element at the same time and/or at different areas of the outer surface.

[0065] Using more than one contacting device allows a more efficient interaction between the cooling device and the glass tube element and, thus, a further improvement of the properties of the glass tube element.

[0066] If some or all of the contacting devices sequentially (spatially and/or in time) come in contact with the outer surface of the glass tube element (wherein the contacting devices do not necessarily all have to contact the same areas of the outer surface of the glass tube element but at least some or all contacting devices may contact different areas of the outer surface of the glass tube element) a graded interaction might be obtained because for example the contact occurs at different temperatures of the outer surface and/or with different interaction devices.

[0067] If some or all of the contacting devices (which are for example spatially distributed) come in contact with the

outer surface of the glass tube element (but e.g. at different areas thereof) at the same time the interaction between the contacting devices and the glass tube element can take place within a small physical volume, hence, the cooling device can be of only reduced size. This is beneficial from an economic point of view.

[0068] In one embodiment it might alternatively or in addition be preferred that two contacting devices, preferably each of two contacting devices, respectively of the plurality of contacting devices, which are arranged down along the path of movement in a consecutive manner have a center-center-distance, preferably measured along the path of movement, of 50 cm or less, more preferably of 40 cm or less, even more preferably of 30 cm or less, even more preferably of 20 cm or less, and most preferably of 10 cm or less.

[0069] It has proven advantageous to allow different distances between adjacent contacting devices down the path of movement. In addition the distances between adjacent contacting devices may vary. Preferably the distance is reduced. This may lead to an increased number of subsequent interactions during higher surface temperatures, which might have more impact on the properties of the glass tube element than interactions at lower surface temperatures. This also allows interaction with the glass tube element within a shorter period of time.

[0070] It has been proven to be advantageous to apply such an increased interaction, even if it comes on cost of a larger setup. The resulting glass tube elements have improved geometric parameters, especially improved first and second ratios, hence improved quality.

[0071] In preferred embodiments the center-center distance between adjacent contacting devices is small or even very small, especially compared to the length of the glass tube element.

[0072] In preferred embodiments the center-center distance between adjacent contacting devices is small or even very small and in addition the glass tube element is rotated while passing the cooling device (especially the contacting device(s)). It has been proven to lead to an improved straightness if many contacting devices are contacting the glass tube element within the cooling device. Especially if the glass tube element (or the outer surface thereof) has a temperature of around T_g while being contacted an improved straightness can be observed.

[0073] In one embodiment it might alternatively or in addition be preferred that at least one of, more than one of, or all of the contacting devices each has, preferably at the same time, contact with two, three, four or more than four areas of the outer surface of the glass tube element by respective contacting areas of the contacting device, wherein preferably the contacting areas and/or the areas of the outer surface contacted by each contacting device are separated from each other.

[0074] If the contacting device is designed such that a plurality of parts of the contacting device interact (e.g. contact) with the glass tube element, especially at the outer surface, an improved, more efficient, more comprehensive and faster control of the cooling process can be obtained.

[0075] In one embodiment it might alternatively or in addition be preferred that at least a third number, preferably two, three, four or five, of the plurality of contacting devices form a contacting device group, wherein the contacting devices of the contacting device group are arranged, preferably in a rotationally symmetrical manner, around the glass tube element, preferably at least some or all of the third number of contacting devices get in contact with the glass tube element at the same time, at different areas of the outer surface of the glass tube element and/or from different spatial directions.

[0076] With appropriate spatial arrangement of the contacting devices a manipulation of the cooling process can be accomplished in a fast and reliable manner. This is true because two or even more contacting devices can get in contact with the glass tube element at the same time and/or from different spatial directions. It has also been proven to have advantageous effects on the properties of the glass tube element if respective arrangements are employed.

[0077] In one embodiment it might alternatively or in addition be preferred that the cooling device, especially the contacting device(s), brings the surface temperature of the glass tube element to $T_g - 200$ degrees C or lower after passing through and/or along the cooling device; and/or wherein at least one or all contacting device(s) has or have, at least in the area where the glass tube element is contacted, especially in the area of the contacting areas, a thermal conductivity of between 1 and 100 W/(m*K), preferably of between 10 and 70 W/(m*K), most preferably of between 30 and 50 W/(m*K).

[0078] By employing a design of the contacting devices with defined thermal conductivity a precise control of the cooling process can be obtained. This allows to improve the quality of the glass tube element.

[0079] In one embodiment it might alternatively or in addition be preferred that at least one of or all of the contacting devices is or are designed as at least one castor, wherein preferably the glass tube element is moveable, supportable, moved and/or supported along the movement path by means of the castor.

[0080] Employing castors allows to have a great design freedom and flexibility. For example different sizes, especially different diameters, different materials, different thermal conductivities and different contacting areas can be achieved with less effort.

[0081] For example in at least one cross-sectional plane of the castor, preferably the plane comprising the center axis of the castor, the castor has at least partially at least one V-like recess.

[0082] This recess allows to realize two contacting areas between the castor and the glass tube element at the same time. In other words, within the space provided by the "V" the glass tube element can be supported by the castor, hence,

the castor provides two side walls which might contact the glass tube element.

[0083] A castor further allows to be utilized as a transport means for moving the glass tube element at the same time. This is very economic.

[0084] It is acknowledged that one or more castors can also be replaced by a respective number of rolls.

[0085] In one embodiment it might be alternatively or in addition preferred that at least one contacting device, especially one or more castors, is temperature-regulated, especially cooled.

[0086] This allows to precisely control the temperature difference between the contacting device and the glass material.

[0087] In one embodiment it might alternatively or in addition be preferred that each castor has at least one contacting area contacting the glass tube element, which contacting area has at least one point which has a distance of 10 cm or less, of 5 cm or less, of 3 cm or less, of 1 cm or less, or of 0.5 cm or less, respectively, from the center axis of the castor.

[0088] It has been proven being advantageous if the contact area of the castor is close to the center axis of the castor. This allows that the size of the castor can be limited with an upper value which in turn lead to compact setups and in addition also yields optimal interaction results.

[0089] In one embodiment it might alternatively or in addition be preferred that each castor has an outer diameter of 50 cm or less, preferably of 30 cm or less, more preferably of 15 cm or less, even more preferably of 10 cm or less, even more preferably of 5 cm or less, even more preferably of 3 cm or less, and most preferably of 1 cm or less.

[0090] It has been proven being advantageous if the size of the castor is limited with an upper value which in turn lead to compact setups and in addition also yields optimal interaction results. The smaller the individual castor is the more castors can be used within small spaces and the more castors can be arranged one after the other. This allows high interaction results.

[0091] In one embodiment it might alternatively or in addition be preferred that at least one of or all of the contacting devices is or are designed as at least one chain and/or at least one belt, wherein preferably the glass tube element is moveable, supportable, supported and/or moved along the movement path by means of the chain or the belt.

[0092] A chain or a belt allow special contacting geometries for controlling the cooling process.

[0093] A chain or a belt further allows to be utilized as a transport means for moving the glass tube element at the same time. This is very economic.

[0094] In one embodiment it might alternatively or in addition be preferred that the plurality of contacting devices can be grouped into at least two groups with respect to at least one aspect of the contacting devices such as quantity, diameter, size, spatial location, center-center-distance, thermal conductivity and/or design, especially castor design, belt design or chain design, wherein preferably for each group the value(s) for the respective aspects each is (are) individually selected from the corresponding options as mentioned hereinabove.

[0095] If different types of contacting devices are used, the interaction between the cooling device and the glass tube element can be tailored to the specific requirements.

[0096] For example for a plurality of contacting devices (e.g. 5 contacting devices) a first group A of contacting devices (e.g. 2 contacting devices) has contacting devices of design A1 (e.g. castor), diameter A2 (e.g. 5 cm), center-center-distance A3 (e.g. 6 cm), spatial location A4 (e.g. centers at 0 cm and 6 cm measured from some reference point) and thermal conductivity A5 (e.g. 30 W/(m*K)). A second group B of contacting devices (e.g. 3 contacting devices) has contacting devices of design B1 (e.g. castor, too), diameter B2 (e.g. 2 cm), center-center-distance B3 (e.g. 3 cm), spatial location B4 (e.g. centers at 10 cm, 13 cm and 16 cm measured, respectively, from the reference point) and thermal conductivity B5 (e.g. 40 W/(m*K)).

[0097] In other words, using for each group all possible combinations of parameters allows an improved manufacturing process, hence, improved properties of the glass tube element.

[0098] In one embodiment it might alternatively or in addition be preferred that the glass tube element is rotated at least during its period of cooling, preferably (i) dependent on the speed of movement, (ii) with a rotation speed of 1 round or more per second, preferably 5 rounds per second or more and/or (iii) with 0.5 or more, preferably with 1 or more, 3 or more, 5 or more or 10 or more, rotations during it is passed through the cooling device.

[0099] Rotating the glass tube element allows to achieve an interaction between the contacting device and the glass tube element around the complete circumference of the glass tube element. Especially, rotating allows a circumferential interaction with only one single contacting device while, of course, also more than one contacting device might be used. This allows to improve the properties of the glass tube element.

[0100] If one or more rotations during the time while the glass tube element is passed through the cooling device is conducted, it can be ensured that indeed at least one complete 360 degree interaction has been carried out for the glass tube element.

[0101] However, it has been found that in certain situations it might be alternatively or in addition preferred that there is no rotation at all.

[0102] The problem is solved by the invention according to a second aspect in that a glass tube element, especially according to the first aspect of the invention, for use as at least one basic part for at least one pharmaceutical container such as a vial, cartridge, ampoule or syringe is proposed.

[0103] It has been surprisingly found that due to the improved properties, a glass tube element according to the inventive concept is predestined for pharmaceutical containers.

[0104] Thus, a glass tube element can be very useful in the manufacturing process of a pharmaceutical container. For example it can be used in the manufacturing process of vials or syringes.

[0105] The problem is solved by the invention according to a third aspect in that a method for producing a glass tube element, especially according to the first aspect of the invention, comprising the steps of:

- Providing a glass tube line;
- Guiding the glass tube line during its period of cooling with a defined speed of movement along a defined, preferably horizontally extending, path of movement, wherein along at least one section of the path of movement at least one cooling device is provided, with the glass tube line having at least temporarily a surface temperature of between T_g-50 and T_g+150 degrees C while passing through and/or along the cooling device;
- Acting at least temporarily and/or area by area by means of the cooling device on at least one part of the glass tube line passing through or along the cooling device for setting up a locally modified cooling rate of the glass tube line; and
- Confectioning of glass tube elements from the glass tube line is proposed.

[0106] It has been surprisingly found that the geometric parameters, hence, each of the first and second ratio and the overall quality of the glass tube element can be improved, if the glass tube line undergoes a special treatment during its period of cooling. It has been proven to lead to advantageous results if the process of cooling is influenced by changing the cooling rate of the glass tube line locally.

[0107] Preferably the cooling rate of the outer surface of the glass tube line is modified. However, also modifications to the cooling rate elsewhere such as within the shell of the glass tube line might be applied.

[0108] If the speed of movement and the path of movement is defined, a higher control of the cooling process can be obtained. Particularly a path of movement which is straight or at least nearly straight has been found as being preferred for a uniform and reproducible interaction.

[0109] The inventors assume that applying the mentioned treatment using the cooling device as well as the other settings, respectively, during the cooling process lead to a manipulation of the structure, especially the structure on, beneath and/or near the outer surface, of the glass tube line which in turn lead to improved geometric properties of the same.

[0110] In one embodiment it might alternatively or in addition be preferred that the cooling device has at least one contacting device, wherein the contacting device has at least from time to time and/or area by area, preferably direct, contact with at least one area of the outer surface of the glass tube line.

[0111] It is the astonishing finding that providing a contacting device allows to control the locally existing cooling rate on the surface, respectively of the outer surface, of the glass tube element in a precise, reliable and comfortable manner. It is also possible to control the instance of time when it contacts the glass tube line. This might be controlled for example by a respective spatial placement of the contacting device within the cooling device, such that the glass tube line passes at an earlier or later instant of time along the respective contacting device. Of course, preferably not the entire contacting device must be in contact with the glass tube line, but it may. Also a part thereof might be sufficient. Of course, not the entire outer surface of the glass tube line must have contact with the contacting device, but it may. Also an area of the outer surface of the glass tube line might be sufficient.

[0112] These design parameters allow to efficiently control the degree of interaction between the contacting device and the glass tube line. The earlier, the longer and the wider the contact between the contacting device and the glass tube line is, the more interaction between both might take place, hence, the more cooling might take place.

[0113] In further preferred embodiments the cooling device has alternatively or in addition at least one fluid dispenser device which is designed to provide a fluid, such as water, fog and/or air, preferably compressed air, preferably at least from time to time and/or area by area, on at least one area of the outer surface of the glass tube line.

[0114] Using a fluid allows an improved control of the cooling process of the glass tube line. Especially a high change of the temperature within short time can be achieved that way. This might also be used for supporting the cooling process carried out by the contacting device.

[0115] Preferably the fluid dispenser is designed at least in part in form of at least one ring nozzle. This allows that a homogeneous (and circumferential) interaction between the fluid and the glass tube line is achieved. In other words, using ring nozzles allows to cover the complete outer surface of the glass tube line. It has been proven that this lead to an improved straightness of the glass tube line at least in sections.

[0116] In also preferred embodiments the fluid dispenser is used as part of an air bearing and/or in combination with

a contacting device. This allows to obtain an interaction with reduced or even without contacting the glass tube line with the contacting device. This may reduce contamination effects.

[0117] In one embodiment it might alternatively or in addition be preferred that at least one of or all of the contacting devices is or are designed as at least one castor, wherein preferably the glass tube element is moveable, supportable, moved and/or supported along the movement path by means of the castor.

[0118] Employing castors allows to have a great design freedom and flexibility. For example different sizes, especially different diameters, different materials, different thermal conductivities and different contacting areas can be achieved with less effort.

[0119] For example in at least one cross-sectional plane of the castor, preferably the plane comprising the center axis of the castor, the castor has at least partially at least one V-like recess.

[0120] This recess allows to realize two contacting areas between the castor and the glass tube element at the same time. In other words, within the space provided by the "V" the glass tube element can be supported by the castor, hence, the castor provides two side walls which might contact the glass tube element.

[0121] A castor further allows to be utilized as a transport means for moving the glass tube element at the same time. This is very economic.

[0122] It is acknowledged that one or more castors can also be replaced by a respective number of rolls.

[0123] Thus, the inventive concept clearly demonstrates that by varying the spatial absolute and relative position of, the number of and/or the diameter of the contacting devices, especially the castors, it is possible to obtain different interaction patterns, hence, to achieve an optimization of the interaction between the cooling device and the glass tube element. This interaction in turn has been identified by the inventors to yield high quality glass tube elements. Thus, for different purposes and requirements respective parameters can be chosen in a comfortable way. This in turn allows to modify and improve ovality and straightness of the glass tube element.

[0124] Of course, it is also possible to change the speed of movement of the glass tube element in order to change the cooling process, hence, the interaction pattern, hence the modification of the ovality and straightness of the glass tube element, thus, improving quality of the glass tube elements. Likewise, it is also possible to change the speed of rotation of the glass tube element in order to change the cooling process, hence, the interaction pattern, hence the modification of the ovality and straightness of the glass tube element, thus, improving quality of the glass tube elements.

[0125] In the following further aspects of the invention are described in detail.

Measuring the optical properties

[0126] The principle of conducting the optical measurements according to the invention is described in further detail below.

[0127] Fig. 1a shows an illustration of a cross-sectional plane of a glass tube element 1 according to the invention. The glass tube element 1 has a shell 3 which has an inner surface 5 and an outer surface 7. The outer surface 7 is the surface of the shell 3 facing away from the lumen 8. The plane is perpendicular to the direction of main extension of the glass tube element 1. The glass tube element is immersed in a fluid 9. It might be sufficient if the fluid 9 surrounds the glass tube element 1 so that only the outer surface 7 is in contact with the fluid 9. However, the fluid 9 might be also inside the hollow cylinder so that it contacts also the inner surface 5 as it is the case for the scenario of Fig. 1a.

[0128] Preferably the fluid has the same optical density as the glass material. The term "the same optical density" here means that the optical density of the fluid and the optical density of the glass material match in three decimal places. Thus, the fluid has the same optical density as the glass material, if the optical density of the fluid and the optical density of the glass material match in three decimal places.

[0129] For example 1.3456 and 1.3454 would be the same optical densities according to that definition. For example 1.3456 and 1.3457 would also be the same optical densities according to that definition. A fluid might comprise or be represented by at least one paraffin or at least one oil, respectively, of appropriate optical density.

[0130] A light ray 11a extends along a measurement path which extends in a direction of measurement perpendicular to the direction of the main extension of the glass tube element 1. The measurement path is within the drawing plane of Fig. 1a. The measurement path is tangent to the surface of the shell 3 facing away from the lumen, i.e. to the outer surface 7. In Fig. 1a the measurement path touches the surface (i.e. the outer surface 7) at a position which can be located within a cylindrical coordinate system (not shown in Fig. 1a) fixedly attached to the glass tube element 1 and having its origin on the center axis (not shown in Fig. 1a) of the glass tube element 1 by means of a height, a radius and an azimuth angle. Assuming that in Fig. 1a at twelve 'o'clock the azimuth angle is zero degrees (and increasing in a clockwise direction), the light ray 11a touches the outer surface 7 at a position having an azimuth angle of 270 degrees.

[0131] If the light ray 11a after passing through the glass tube element 1, especially through the shell 3, is analyzed using known optical measurement means (not shown in Fig. 1a) a certain value of the optical delay the light ray 11a experienced (inter alia) within the glass tube element 1 can be determined. This optical delay is created due to double refraction in the glass tube element 1 which in turn depends on the mechanical stress state in the respective domains

of the shell 3 the light ray 11a passes. Consequently, the optical delay can be regarded as a measure for the stresses in the surface of the shell 3, such as in the outer surface 7 of the shell 3. For different measurements, different positions are chosen where the measurement path touches the outer surface 7 of the shell 3 in the same cross-sectional plane (i.e. for the same height in the coordinate system). In other words, the azimuth angle of the position changes for each measurement.

[0132] Thus, if for different measurements the azimuth angle is changed, for example in steps of 1 degree from 0 degrees to 359 degrees, (e.g. by rotating the glass tube element around its center axis in Fig. 1a) the optical delay of the light ray 11a for different azimuth angles, hence, for different positions where the measurement path touches the outer surface 7, can be determined in an easy and reliable manner. It is easy to obtain from these measurements the size of the range within which the values of the optical delay for the different azimuth angles fall. For example, if for five measurements at five different azimuth angles the values for the optical delay is, respectively, 40 nm, 45 nm, 50 nm, 55 nm and 60 nm, then the corresponding range is 40 nm through 60 nm and the size of the range is $(60 \text{ nm} - 40 \text{ nm}) = 20 \text{ nm}$.

[0133] Fig. 1b shows a plot of the optical delay (in nanometers) over the azimuth angle (in degrees) for the glass tube element 1 of Fig. 1a. It is apparent that for the glass tube element 1 according to the invention, the course of the graph is quite flat and that the values of the optical delay the light ray 11a experiences all fall within a range having a size of between 3 nm and 30 nm. In other words, the difference between the minimal and maximal value of the optical delays obtained from the different measurements is between 3 nm and 30 nm.

[0134] Just for the sake of completeness it is acknowledged that Fig. 1c shows an illustration of a plot representing the relative course of the optical delay obtained for the glass tube element 1 for measurement paths which are shifted parallel to the measurement path of light ray 11a between the outer surface 7 and the inner surface 5 of the shell 3 (i.e. having a fixed height, a fixed azimuth angle but different radii). The maximum of the plot in Fig. 1c is at an optical delay of 20.57 nm and corresponds to a measurement with light ray 11a. The minimum of the plot in Fig. 1c is at an optical delay of -28.04 nm and corresponds to a measurement with light ray 1 1b which follows a path that is tangent to the inner surface 5 (see Fig. 1a). The distance between the position of, respectively, the maximum peak and the minimum peak, corresponds to the thickness of the shell 3, which is 1 mm.

[0135] For example, for the optical measurements, the light ray, such as the light ray 11a described above, has a linear polarization which encloses an angle of 45 degrees with the center axis of the glass tube element. For example, the light ray has light of wavelength 630 nm, 633 nm or 635 nm. For example the ambient temperature is room temperature.

Further glass properties

[0136] The coefficient of linear thermal expansion (CTE) is a measure of characterizing the expansion behavior of a glass when it experiences certain temperature variation. CTE may be the average linear thermal expansion coefficient in a temperature range of from 20°C to 300°C as defined in DIN ISO 7991:1987. The lower the CTE, the less expansion with temperature variation. Therefore, in the temperature range of from 20°C to 300°C the glass of the wall of the glass tube element of the present invention preferably has a CTE of less than 12 ppm/K, more preferably less than 10.0 ppm/K, more preferably less than 9.0 ppm/K, more preferably less than 8.0 ppm/K, more preferably less than 7 ppm/K, more preferably less than 6.5 ppm/K. However, the CTE should also not be very low. Preferably, in the temperature range of from 20°C to 300°C the CTE of the glasses of the present invention is more than 3 ppm/K, more preferably more than 4 ppm/K, more preferably more than 5 ppm/K, more preferably more than 6 ppm/K. In order for the glasses to be well suitable for chemical toughening, the glasses may contain relatively high amounts of alkali metal ions, preferably sodium ions. However, thereby the average linear thermal expansion coefficient CTE in the temperature range between 20°C and 300°C is increased. Preferably, the glass of the wall of the glass tube element of the invention has a CTE higher than $7 \cdot 10^{-6}/^{\circ}\text{C}$, more preferably higher than $8 \cdot 10^{-6}/^{\circ}\text{C}$, more preferably higher than $9 \cdot 10^{-6}/^{\circ}\text{C}$. However, a high CTE also complicates production of the glasses by direct hot-forming. Therefore, the glasses preferably have a CTE lower than $13 \cdot 10^{-6}/^{\circ}\text{C}$.

[0137] The transition temperature of the glass used for the wall of the glass tube element may be higher than 300 °C, higher than 500 °C, higher than 520 °C, higher than 530 °C, higher than 550 °C, or even higher than 600 °C. The transition temperature of the wall of the glass tube element may be lower than 900 °C, lower than 800 °C, lower than 700 °C, lower than 650 °C, or lower than 630 °C. Generally, a low transition temperature usually includes lower energy costs for melting the glass and for processing. Also, the glass will usually have a lower fictive temperature if the transition temperature is low. Hence, the glass will be less prone to irreversible thermal shrinkage during optional chemical toughening, if the transition temperature is higher.

[0138] The glass tube element should be manufactured with a high purity and it should feature a good resistance, especially against alkaline solutions. The resistance against alkaline solutions is important for the use of glass tube elements. Alkaline solutions are often used as cleaning agents for glass tube elements. Preferably, the glass tube element has an alkaline resistance according to DIN ISO 695:1994 of class A3, of A2, or even of A1. Alkaline resistance means resistance to attack by aqueous alkaline solutions at 50 °C. High chemical stability and/or a high alkaline resistance

will lead to strongly reduced precipitation or leakage of substances out of the glass tube element for example when the glass tube element is in contact with fluids such as juice, tea or dishwasher water. Leakage of substances out of the glass tube element will change the chemical composition of the surface of the glass from which substances have leaked. This might lead negative effects on the appearance and should therefore be avoided.

[0139] The average surface roughness (R_a) is a measure of the texture of a surface. It is quantified by the vertical deviations of a real surface from its ideal form. Commonly amplitude parameters characterize the surface based on the vertical deviations of the roughness profile from the mean line. R_a is arithmetic average of the absolute values of these vertical deviations. The roughness can be measured with atomic force microscopy. The inner surface and/or outer surface of the glass tube element preferably has an average surface roughness R_a of less than 30 nm, of less than 10 nm, of less than 5 nm, of less than 2 nm, of less than 1 nm. In some embodiments, the surface roughness R_a is less than 0.5 nm. A smaller inner and/or outer surface roughness reduces the amount residual fluid. Residual fluid within the glass tube element can give rise to growth of microorganisms which could harm the health of animals or humans. Furthermore, a smaller outer surface roughness gives a more pleasant feeling when holding the glass tube element in the hand. The mentioned roughness values can be obtained by fire-polishing the glass.

Glass compositions

[0140] The glass used for the wall of the glass tube element is not limited to a specific glass composition. The glass may be selected from the group consisting of soda-lime glass, borosilicate glass, alkaline-resistant glass and aluminosilicate glass. Optionally, a borosilicate glass is used.

[0141] The glass of the glass tube element preferably comprises the following components in the indicated amounts (in wt.%):

Component	Content (wt.%)
SiO_2	40 to 85
Al_2O_3	0 to 25
Na_2O	0 to 18
K_2O	0 to 15
MgO	0 to 10
B_2O_3	0 to 22
Li_2O	0 to 10
ZnO	0 to 5
CaO	0 to 16
BaO	0 to 12
ZrO_2	0 to 5
CeO_2	0 to 0.5
SnO_2	0 to 3
P_2O_5	0 to 15
Fe_2O_3	0 to 1.5
TiO_2	0 to 10
SrO	0 to 1
F	0 to 1
Cl	0 to 1

[0142] SiO_2 is a relevant network former that can be used in the glass used for this of the invention. Therefore, the glasses may comprise SiO_2 in an amount of at least 60 wt.%. More preferably, the glass comprises SiO_2 in an amount of at least 62 wt.%, at least 65 wt.%, at least 68 wt.%, more than 70 wt.%, or even more than 75 wt.%. However, the content of SiO_2 in the glass should also not be extremely high because otherwise the meltability may be compromised.

The amount of SiO_2 in the glass may be limited to at most 85 wt.%, or at most 82 wt.%. In embodiments, the content of SiO_2 in the glass is from 60 to 85 wt.%, or from >65 to 75 wt.%.

[0143] B_2O_3 may be used in order to enhance the network by increasing the bridge-oxygen in the glass via the form of $[\text{BO}_4]$ tetrahedra. It also helps to improve the damage resistance of the glass. However, B_2O_3 should not be used in high amounts in the glass since it can decrease the ion-exchange performance. Furthermore, addition of B_2O_3 can significantly reduce the Young's modulus. The glass may comprise B_2O_3 in an amount of from 0 to 20 wt.%, preferably from 0 to 15 wt.%, preferably from 0.1 to 13 wt.%. In embodiments, the glass preferably comprises at least 5 wt.%, more preferably at least 7 wt.%, or at least 10 wt.% of B_2O_3 .

[0144] P_2O_5 may be used in the glass of the invention in order to help lowering the melting viscosity by forming $[\text{PO}_4]$ tetrahedra, which can significantly lower the melting point without sacrificing anti-crystallization features. Limited amounts of P_2O_5 do not increase geometry variation very much, but can significantly improve the glass melting, forming performance, and ion-exchanging (chemical toughening) performance. However, if high amounts of P_2O_5 are used, geometry expansion upon chemical toughening may be increased significantly. Therefore, the glasses may comprise P_2O_5 in an amount of from 0 to 4 wt.%, or from 0 to 2 wt.%. In some embodiments, the glass is free of P_2O_5 .

[0145] It is believed that Al_2O_3 can easily form tetrahedra coordination when the alkaline oxide ratio content is equal or higher than that of Al_2O_3 . $[\text{AlO}_4]$ tetrahedra coordination can help building up more compact network together with $[\text{SiO}_4]$ tetrahedra, which can result in a low geometry variation of the glass. $[\text{AlO}_4]$ tetrahedra can also dramatically enhance the ion-exchange process during chemical toughening. Therefore, Al_2O_3 is preferably contained in the glasses in an amount of at least 0 wt.%, more preferably of more than 1 wt.%, more preferably of more than 4 wt.%. However, the amount of Al_2O_3 should also not be very high because otherwise the viscosity may be very high so that the meltability may be impaired. Therefore, the content of Al_2O_3 in the glasses is preferably at most 20 wt.%, at most 12 wt.%, or at most 10 wt.%. In preferred embodiments, the content of Al_2O_3 in the glasses is from 0 to 20 wt.%, from 1 to 12 wt.%, from 4 to 10 wt.%.

[0146] TiO_2 can also form $[\text{TiO}_4]$ and can thus help building up the network of the glass, and may also be beneficial for improving the acid resistance of the glass. However, the amount of TiO_2 in the glass should not be very high. TiO_2 present in high concentrations may function as a nucleating agent and may thus result in crystallization during manufacturing. Preferably, the content of TiO_2 in the glasses is from 0 to 10 wt.%, or up to 7 wt.%. In some embodiments, the glass comprises at least 0.5 wt.%, at least 2 wt.%, or at least 3 wt.% of TiO_2 . In an embodiment, the glass is free of TiO_2 .

[0147] ZrO_2 has the functions of lowering the CTE and improving the alkaline resistance of a glass. It may increase the melting viscosity, which can be suppressed by using P_2O_5 . Like alkaline metals, Zr^{4+} is also a network modifier. Furthermore, ZrO_2 is a significant contributor for increased Young's modulus. Preferably, the content of ZrO_2 in the glasses is from 0 to 5 wt.%, up to 2 wt.%. The glass may be free of ZrO_2 . In some embodiments, the glass comprises at least 0.1 wt.%, or at least 0.2 wt.% ZrO_2 .

[0148] Alkaline oxides R_2O ($\text{Li}_2\text{O} + \text{Na}_2\text{O} + \text{K}_2\text{O} + \text{Cs}_2\text{O}$) may be used as network modifiers to supply sufficient oxygen anions to form the glass network. Preferably, the content of R_2O in the glasses is more than 4 wt.%, or more than 12 wt.%. However, the content of R_2O in the glass should not be very high because otherwise chemical stability and chemical toughenability may be impaired. Preferably, the glasses comprise R_2O in an amount of at most 30 wt.%, at most 25 wt.%, or at most 20 wt.%. Other embodiments are free of alkaline oxides, or at least free of Na_2O , K_2O , Cs_2O and/or Li_2O .

[0149] Li_2O can help improving the Young's modulus and lowering CTE of the glass. Li_2O also influences the ion-exchange greatly. It was surprisingly found that Li-containing glass has a smaller geometry variation. Therefore, the content of Li_2O in the glasses may be set to at least 0 wt.%, or more than 5 wt.%, or even more than 10 wt.%. However, the content of Li_2O should not be very high because otherwise chemical stability and chemical toughenability may be impaired. Preferably, the content of Li_2O in the glasses is at most 24 wt.%, less than 15 wt.%, or even 0 wt.%.

[0150] Na_2O may be used as a network modifier. However, the content of Na_2O should not be very high because otherwise chemical stability and chemical toughenability may be impaired. Preferably, the content of Na_2O in the glasses is from 0 to 15 wt.%, preferably from 2 to 15 wt.%. In preferred embodiments, the content of Na_2O in the glasses is at least 5 wt.%, at least 8 wt.%, or at least 10 wt.%.

[0151] K_2O may be used as a network modifier. However, the content of K_2O should not be very high because otherwise chemical stability and chemical toughenability may be impaired. Preferably, the content of K_2O in the glasses is from 0 to 15 wt.%, or from >0.5 to 7 wt.%. The glass may be free of K_2O .

[0152] Preferably, the glasses comprise more Na_2O than K_2O . Thus, preferably the molar ratio $\text{Na}_2\text{O}/(\text{Na}_2\text{O} + \text{K}_2\text{O})$ is from >0.5 to 1.0, from >0.6 to 1.0, from >0.7 to 1.0, or from >0.8 to 1.0.

[0153] Preferably, the content of the sum of Li_2O and Na_2O in the glasses is more than 10 mol.%, or more than 15 mol.%. However, the content of the sum of Li_2O and Na_2O in the glasses should not be very high. Preferably, the content of the sum of Li_2O and Na_2O in the glasses is at most 25 mol.%, or at most 20 mol.%.

[0154] The glasses may also comprise alkaline earth metal oxides as well as ZnO which are collectively termed "RO" in the present specification. Alkaline earth metals and Zn may serve as network modifiers. Preferably, the glasses comprise RO in an amount of from 0 to 20 wt.%, preferably from 0 to 15 wt.%. In some embodiments, the glass preferably

comprises at least 0.5 wt.%, more preferably at least 1 wt.%, more preferably at least 5 wt.% of RO. Preferred alkaline earth metal oxides are selected from the group consisting of MgO, CaO, SrO und BaO. More preferably, alkaline earth metals are selected from the group consisting of MgO und CaO. More preferably, the alkaline earth metal is MgO. Preferably, the glass comprises MgO in an amount of from 0 to 10 wt.%. In some embodiments, the glass comprises at least 0.5 wt.%, at least 1 wt.%, or at least 2 wt.% of MgO. Preferably, the glass comprises CaO in an amount of from 0 to 16 wt.%, preferably from 0 to 13 wt.%, preferably from 0 to 10 wt.%. In some embodiments, the glass comprises at least 0.5 wt.%, at least 1 wt.%, at least 5 wt.%, at least 10 wt.%, or at least 12 wt.% of CaO. Preferably, the glass comprises BaO in an amount of from 0 to 12 wt.%, preferably from 0 to 10 wt.%. In some embodiments, the glass comprises at least 0.5 wt.%, at least 2 wt.%, or at least 7 wt.% of BaO. The glass may be free of BaO, MgO and/or CaO.

[0155] Preferably, the glass comprises ZnO in an amount of from 0 to 5 wt.%. In some embodiments, the glass comprises at least 0.5 wt.%, at least 1 wt.%, or at least 2 wt.% of ZnO. In other embodiments, the glass is free of ZnO. Preferably, the content of the sum of MgO and ZnO in the glasses is from 0 to 10 wt.%. In some embodiments, the content of the sum of MgO and ZnO in the glasses at least 0.5 wt.%, more preferably at least 1 wt.%, more preferably at least 2 wt.%.

[0156] At the end, when forming a glass by mixing different types of the oxides, the integrated effect should be considered to achieve a glass with comparatively low expansion, which is supported by high densification of the glass network. It means, in addition to $[\text{SiO}_4]$ tetrahedral $[\text{BO}_4]$ tetrahedra, $[\text{AlO}_4]$ tetrahedra, or $[\text{PO}_4]$ tetrahedra are expected to help connect the $[\text{SiO}_4]$ more effectively rather than other type of polyhedrons. In other words, $[\text{BO}_3]$ triangle and $[\text{AlO}_6]$ octahedron, for instance, are not preferred. It means, sufficient oxygen anions are preferable to be offered by adding proper amounts of metal oxides, such as R_2O and RO.

[0157] Preferably, the content of SnO_2 in the glasses is from 0 to 3 wt.%. More preferably, the glasses are free of SnO_2 . Preferably, the content of Sb_2O_3 in the glasses is from 0 to 3 wt.%. More preferably, the glasses are free of Sb_2O_3 . Preferably, the content of CeO_2 in the glasses is from 0 to 3 wt.%. High contents of CeO_2 are disadvantages because CeO_2 has a coloring effect. Therefore, more preferably, the glasses are free of CeO_2 . Preferably, the content of Fe_2O_3 in the glasses is from 0 to 3 wt.%. More preferably, the glasses are free of Fe_2O_3 .

[0158] The glass described herein is described as having a composition of different constituents. This means that the glass contains these constituents without excluding further constituents that are not mentioned. However, in preferred embodiments, the glass consists of the components mentioned in the present specification to an extent of at least 95%, more preferably at least 97%, most preferably at least 99%. In most preferred embodiments, the glass essentially consists of the components mentioned in the present specification.

[0159] Optionally, coloring oxides can be added, such as Nd_2O_3 , Fe_2O_3 , CoO, NiO, V_2O_5 , MnO_2 , CuO, CeO_2 , Cr_2O_3 .

[0160] 0-2 wt.% of As_2O_3 , Sb_2O_3 , SnO_2 , SO_3 , Cl and/or F could be also added as refining agents. 0-5 wt.% of rare earth oxides could also be added to add optical or other functions to the glass wall.

[0161] The terms "X-free" and "free of component X", or "0 % of X", respectively, as used herein, refer to a glass, which essentially does not comprise said component X, i.e. such component may be present in the glass at most as an impurity or contamination, however, is not added to the glass composition as an individual component. This means that the component X is not added in essential amounts. Non-essential amounts according to the present invention are amounts of less than 100 ppm, preferably less than 50 ppm and more preferably less than 10 ppm. Preferably, the glasses described herein do essentially not contain any components that are not mentioned in this description.

[0162] In embodiments, the glass used for the glass tube element has the following composition in percent by weight:

Component	Content (wt.%)
SiO_2	40 to 85
Al_2O_3	0 to 25
Na_2O	2 to 18
K_2O	0 to 15
MgO	0 to 10

Cutting mechanism

[0166] In preferred embodiments at least one out of three cutting mechanisms might be applied for manufacturing the glass tube elements, i.e. to prepare the desired length of each glass tube element from a longer glass element such as a glass tube line: 1. scratching, which means that at desired positions the longer glass element is scratched and broken in order to obtain the individual glass tube elements. This technique might be also referred to as "score broken". 2. Sawing, which means that at the desired positions the longer glass element is sawed so that individual glass tube elements are obtained. 3. Laser cutting, which means that the individual glass tube elements are obtained in that a laser cuts the individual pieces from the longer glass element.

[0167] In preferred embodiments a laser cutting technique is employed.

Polishing

[0168] In preferred embodiments all or at least one or more parts of the glass tube elements can be made subject to fire polishing. This means that the material is exposed to a flame or heat, for example during drawing of the glass tube or afterwards. This might result in a smoothening of the surface. Preferably at least the end sections of the glass tube elements are fire polished. More preferably the entire glass tube element is fire polished, at least its outer surface. Reference is also made to the discussion made with respect to surface roughness above.

Brief description of the figures

[0169] Various aspects of this invention will become apparent to those skilled in the art from the following detailed description of preferred embodiments, when read in light of the accompanying schematic drawings, wherein

Fig. 2 shows a glass tube element according to the invention;

Fig. 3 shows a schematic illustration of a first exemplary production line;

Fig. 4 shows a schematic cross-sectional view of a contacting device;

Fig. 5 shows a schematic illustration of a second exemplary production line;

Fig. 6 shows a schematic illustration of a third exemplary production line;

Fig. 7 shows a schematic illustration of a fourth exemplary production line;

Fig. 8 shows a schematic illustration of a fifth exemplary production line;

Detailed description of the figures

[0170] Fig. 2 shows a glass tube element 101 according to the invention.

[0171] It has a hollow cylindrical form (not only a section thereof, but entirely) and a shell 103 which encloses a lumen 105. The length (this is, from top to bottom) of the glass tube element 101 is 1.5 m. The nominal outer diameter of the glass tube element 101 is 24 mm. The shell 103 has an average thickness T of 1 mm. The glass tube element 101 extends along a direction R.

[0172] When conducting optical measurements on the glass tube element 101 by means of at least one light ray which extends along a measurement path, which measurement path extends in a direction of measurement perpendicular to the direction of the main extension of the glass tube element 101 and which measurement path is tangent to the surface of the shell 103 facing away from the lumen 105, namely the outer surface of the shell 103, and which measurement path touches the surface for different measurements at different positions each having a different azimuth angle within a cylindrical coordinate system fixedly attached to the glass tube element 101 and having its origin on the center axis of the glass tube element 101, the optical delays of the light ray obtained from the different measurements have values

which all fall within a range having a size of between 3 and 30 nm.

[0173] Fig. 3 shows a schematic illustration of a first exemplary production line for producing a glass tube element such as the glass tube element 51 or 51'.

[0174] A glass tube line 111 formed by some forming device 113 is redirected into a horizontal direction. The forming device 113 is not specified in more detail here, but it may be designed for conducting for example a Danner process or a Vello process.

[0175] It is acknowledged that the glass tube element is part of the glass tube line 111. Alternatively it might be stated that the glass tube element during its production process is connected to further glass tube elements in one piece. From the glass tube line 111 subsequently glass tube elements, such as the glass tube element 101, are confectioned.

[0176] Therefore, even if reference is made to the glass tube line 111, the person skilled in the art clearly understands that every treatment the glass tube line 111 undergoes is also applied to the glass tube elements because these elements correspond to respective sections of the glass tube line 111. Vice versa the same is true: If it is stated that a glass tube element is treated somehow, this is the same as if the glass tube line, from which the glass tube element has been confectioned, is treated that way (unless otherwise stated or evident from the context).

[0177] Starting from a Position of $x=0$ (see Fig. 3) the glass tube line 111 runs in a horizontal direction parallel to the x axis corresponding to a defined path of movement. The glass tube line 111 has a defined speed of movement, preferably of 30 cm/s. The glass tube line 111, hence the glass tube element corresponding to the respective section of the glass tube line 111, passes with the defined speed of movement through a cooling device 115, for setting up a locally modified cooling rate of the glass tube line 111 (hence the glass tube elements). The glass tube line 111 has at least temporarily a surface temperature of between T_g-50 and T_g+150 degrees C while passing through the cooling device 115. T_g means the transition temperature.

[0178] The cooling device 115 has a plurality of four contacting devices 117a-117d. Each contacting device 117a-117d is designed in form of a castor. The contacting devices 117a-117d has at least from time to time direct contact with at least one area of the outer surface of the glass tube line 111 (hence the corresponding glass tube elements).

[0179] To be more precise, the four contacting devices 117a-117d comes in contact with the outer surface of the glass tube element (i.e. the respective section of the glass tube line 111) one after another in time. A section of the glass tube line 111 corresponding to a glass tube element such as the glass tube element 51 or 51' first comes in contact with contacting device 117a, then with contacting device 117b, then with contacting device 117c, and finally with contacting device 117d. Of course, this does not exclude that more than one contacting device has contact at the same time with the outer surface.

[0180] The locally modified cooling rate of the glass tube line 111 is achieved by means of the contacting devices 117a-117d. The contacting devices 117a-117d all have, at least in the area where the glass tube line 111 is contacted, a thermal conductivity of between 1 and 100 W/(m*K). Indeed, it is preferably between 30 and 50 W/(m*K). This allows to manipulate and change the cooling rate.

[0181] Changing the cooling rate has been proven to lead to increased homogeneity of the optical delay, hence to improved quality of the glass tube element.

[0182] The contacting devices 117a-117d are located at spatial positions P1 ... P4 down along the path of movement in a consecutive manner. Each of two contacting devices arranged in a consecutive manner (i.e. preferably they are direct neighbors) have a center-center-distance, preferably measured along the path of movement, of 50 cm or less. Indeed, the center-center-distance is 50 cm. Further contacting devices 119a-119d are provided at spatial positions P5..P8.

[0183] Fig. 4 shows a schematic cross-sectional view of a contacting device, such as castor, for example castor 117a. The view is obtained by a cutting plane perpendicular to the x axis in Fig. 2 such that the view comprises the center axis of the contacting device.

[0184] The castor 117a (and likewise castors 117b-117d) have a V-like recess, which allows to support and/or move the glass tube line 111 along the path of movement. This shaping allows that the contacting device, such as the castor 117a, has at the same time contact with two areas 121a, 121b of the outer surface of the glass tube line 111 (hence the glass tube elements) by respective contacting areas of the contacting device. The contacting areas and the areas of the outer surface 121a, 121b contacted by the contacting device 117a are separated from each other.

[0185] The areas 121a, 121b are produced by surface areas of the castors, i.e. the contacting areas, which have at least one point which in turn has a distance $D/2$ of 10 cm or less from the center axis of the castor 117a.

[0186] Once the glass tube line 111 (or a section thereof corresponding to a glass tube element) exits the cooling device 115, the glass tube line 111 has a surface temperature of less than T_g-50 degrees C. Of course, this is not necessary and it may still has a surface temperature of between T_g-50 and T_g+150 degrees C. However, in the preferred setup the temperature is below T_g-50 degrees C. This is true because in this case, subsequent contacts of the glass tube line 111 with other elements have no or no significant or at least no adverse effect on any preferred properties of the glass tube line 111 (hence, the glass tube elements).

[0187] Indeed, in the setup of Fig. 3, following the cooling device 115, the glass tube line 111 get in contact with the

further castors 119a-119d provided at spatial positions P5..P8 down along the path of movement in a consecutive manner. However, they might be different from the castors 117a-117d comprised by the cooling device 115 because they are not part of the cooling device 115 and are not used for manipulating the cooling characteristics of the glass tube line 111.

[0188] Of course, in other preferred embodiments the castors 119a-119d might correspond to contacting devices of a second cooling device.

[0189] As indicated by the circular arrow in Fig. 3, the glass tube line 111 is rotated during its period of cooling with a rotation speed of 1 round or more per second. Indeed, the glass tube line 111 is rotated the entire time until confectioning, hence, also during the period of cooling.

[0190] Downstream of some transport device 123, the glass tube line 111 is confectioned so that individual glass tube elements, such as the glass tube element 101, are obtained from that line with a desired length.

[0191] Fig. 5 shows a schematic illustration of a second exemplary production line for producing a glass tube element such as the glass tube element 101. Structural features of the second exemplary production line which are identical or similar to the structural features of the first exemplary production line are labeled in Fig. 5 with the same reference numerals, but with a single dash.

[0192] It is apparent that the second exemplary production line is largely similar to the first exemplary production line described with respect to Fig. 3. Therefore, only differences between the first and second exemplary production line need to be discussed here. In addition, reference can be made to the above explanations with respect to Fig. 3.

[0193] The production line of Fig. 5 comprises a cooling device 115' which has a plurality of five contacting devices 117a'-117e'.

[0194] The contacting devices 117a'-117e' are located at spatial positions P1' ... P5' down along the path of movement in a consecutive manner. Each of two contacting devices arranged in a consecutive manner (i.e. preferably they are direct neighbors) have a center-center-distance, preferably measured along the path of movement, of 50 cm or less. Indeed, the center-center-distance is 30 cm.

[0195] This means, there has been added one contacting device 117e'. And the center-center-distance between adjacent contacting devices 117a'-117e' has been reduced from 50 cm to 30 cm.

[0196] This setup allows an increased interaction between the cooling device 115' and the glass tube line 111' during the period of cooling.

[0197] It has been proven to be advantageous to apply such an increased interaction, even if it comes on cost of a larger setup. The resulting glass tube elements have improved quality of the glass tube element due to the stress distribution which lead to a homogeneous optical delay.

[0198] The further castors 119a'-119e' at spatial positions P6'..P10' are not comprised by the cooling device 115'.

[0199] Fig. 6 shows a schematic illustration of a third exemplary production line for producing a glass tube element such as the glass tube element 101. Structural features of the third exemplary production line which are identical or similar to the structural features of the first and/or second exemplary production line are labeled in Fig. 6 with the same reference numerals, but with a double dash.

[0200] It is apparent that the third exemplary production line is largely similar to the first and second exemplary production line described with respect to Fig. 3 and Fig. 5. Therefore, only differences between the first, second and third exemplary production line need to be discussed here. In addition, reference can be made to the above explanations with respect to Fig. 3 and Fig. 5.

[0201] The production line of Fig. 6 comprises a cooling device 115" which has a plurality of five contacting devices 117a"-117e" located at spatial position P1"..P5" down along the path of movement in a consecutive manner.

[0202] The plurality of contacting devices 117a"-117e" can be grouped into two groups with respect to the aspects diameter and center-center-distance.

[0203] The first group comprises contacting devices 117a"-117d" at spatial positions P1"..P4" and the second group comprises contacting device 117e" at spatial position P5". The contacting devices 117a"-117d" of the first group have a smaller diameter than the contacting device 117e' of the second group. The smaller diameter allows that the center-center-distance of adjacent contacting devices 117a"-117d" is reduced to 3 cm.

[0204] This setup allows an increased interaction between the cooling device 115" and the glass tube line 111" during the period of cooling. It has been proven to be advantageous to have contacting devices which are closer together. Hence, by reducing the size, especially the diameter of a contacting device which is designed as a castor, more contacting devices can be applied during higher temperatures.

[0205] Since in the setup of Fig. 6 different castors are used, different interactions are obtained based inter alia on: Time of first contact and castor diameter.

[0206] Fig. 7 shows a schematic illustration of a fourth exemplary production line for producing a glass tube element such as the glass tube element 101. Structural features of the fourth exemplary production line which are identical or similar to the structural features of the first, second and/or third exemplary production line are labeled in Fig. 7 with the same reference numerals, but with a triple dash.

[0207] It is apparent that the fourth exemplary production line is largely similar to the first, second and third exemplary production line described with respect to Fig. 3, Fig. 5 and Fig. 6. Therefore, only differences between the first, second, third and fourth exemplary production line need to be discussed here. In addition, reference can be made to the above explanations with respect to Fig. 3, Fig. 5 and Fig. 6.

[0208] The production line of Fig. 7 comprises a cooling device 115''' which has a plurality of six contacting devices 117a'''-117f''' located at spatial positions P1'''..P6''' down along the path of movement in a consecutive manner.

[0209] The plurality of contacting devices 117a'''-117f''' can be grouped into two groups with respect to the aspects diameter and center-center-distance.

[0210] The first group comprises contacting devices 117b'''-117d''' at spatial positions P2'''..P4''' and the second group comprises contacting devices 117a''' and 117f''' at spatial position P1''' and P5'''. The contacting devices 117b'''-117d''' of the first group have a smaller diameter than the contacting devices 117a''' and 117f''' of the second group. The smaller diameter allows that the center-center-distance of adjacent contacting devices 117b'''-117d''' is reduced to 3 cm.

[0211] The arrangement of the contacting devices 117a'''-117f''' is such that the class tube line 111''' comes in contact first with the contacting device 117a''' of the second group than one after the other of contacting devices 117b'''-117d''' of the first group and finally with contacting device 117e''' of the second group.

[0212] In other words, the first interaction between the class tube line 111''' and the cooling device 115''' is by means of the contacting device 117a''' which has a large diameter. Then the interaction takes place by means of the contacting devices 117b'''-117e''' which have smaller diameters. Finally interaction takes place with the contacting device 117f''' having a larger diameter.

[0213] The further castors 119a'''-119d''' at spatial positions P6'..P10' are not comprised by the cooling device 115'''.

[0214] Fig. 8 shows a schematic illustration of a fifth exemplary production line for producing a glass tube element such as the glass tube element 101. Structural features of the fifth exemplary production line which are identical or similar to the structural features of the first, second, third and/or fourth exemplary production line are labeled in Fig. 8 with the same reference numerals, but with a fourth-times dash.

[0215] The fifth exemplary production line is based particularly on the fourth exemplary production line described with respect to Fig. 7. Therefore, only differences between the fourth and fifth exemplary production line need to be discussed here. In addition, reference can be made to the above explanations with respect to Fig. 7.

[0216] The production line of Fig. 8 comprises a cooling device 115'''' which in turn has a plurality of seven contacting devices 117a''''-117g'''' located at spatial positions P1''''..P6'''' down along the path of movement in a consecutive manner. Indeed, with 117a'''' two contacting devices located both at P1'''' are denoted which form a contacting device group. The contacting devices 117a'''' of the contacting device group are arranged in a rotationally symmetrical manner around the glass tube line 111 (hence, around glass tube element 101).

[0217] In other words, one of the two contacting devices 117a'''' are located horizontal above and the other horizontal below the glass tube line 111''''.

[0218] This is just a further design option for increasing the number of interaction elements, especially contacting devices. This allows that at spatial position P1'''' four contacting surfaces interact between the cooling device 115'''' and the glass tube line 111'''' with only little space requirements and consumption: Two contacting devices 117a'''' each having two contacting areas (see description with respect to Fig. 4).

[0219] The features disclosed in the description, the figures as well as the claims could be essential alone or in every combination for the realization of the invention in its different embodiments.

30

Claims

1. A glass tube element comprising
at least one section which is of hollow cylindrical form, wherein the section has at least one shell which encloses at
35 least one lumen;
wherein when conducting optical measurements on the glass tube element by means of at least one light ray which
extends along a measurement path, which measurement path extends in a direction of measurement perpendicular
to the direction of the main extension of the glass tube element and which measurement path is tangent to the
surface of the shell facing away from the lumen and which measurement path touches the surface for different
40 measurements at different positions each having a different azimuth angle within a cylindrical coordinate system
fixedly attached to the glass tube element and having its origin on the center axis of the glass tube element, the
optical delays of the light ray obtained from the different measurements have values which all fall within a range
having a size of between 3 and 30 nm.
- 45 2. The glass tube element according to claim 1,
wherein the light ray comprises a wavelength of between 250 and 900 nm, preferably between 390 and 800 nm,
most preferably 394 nm or 633 nm.
3. The glass tube element according to any one of the preceding claims,
50 wherein the glass tube element is surrounded by at least one fluid such that at least the surface of the shell facing
away from the lumen is in contact with the fluid.
4. The glass tube element according to any one of the preceding claims,
wherein the glass tube element is completely immersed in the at least one fluid such that at least the surface of the
55 shell facing away from the lumen and the surface of the shell facing towards the lumen, both, are in contact with
the fluid.
5. The glass tube element according to claim 3 or 4,

wherein the fluid has, preferably for the wavelength of the light ray, an optical density which is at most 1% different compared to the optical density of the glass material of the glass tube element.

6. The glass tube element according to any one of the claims 3 to 5,
wherein the fluid has, preferably for the wavelength of the light ray, an optical density of between 1.2 and 2.5, preferably between 1.3 and 1.7 and most preferably 1.362, 1.460, 1.463, 1.472, 1.473, 1.474, 1.486, between 1.492 and 1.493, 1.497, 1.501, 1.516, 1.525 or between 1.43 and 1.61.
7. The glass tube element according to any one of the claims 3 to 6,
wherein the fluid comprises ethyl alcohol, olive oil, carbon tetrachloride, sunflower oil, terpentine, glycerine, furfuryl alcohol, dibutylphtalat 84-74-2, toluol, benzene, dimethyphtalate, monochlorobenzene or silicon oil or any combination thereof.
8. The glass tube element according to any one of the preceding claims,
wherein the optical delays of the light ray obtained from the different measurements have values which all fall within a range of between 10 and 150 nm, preferably between 20 and 100 nm, and/or wherein the optical delays of the light ray obtained from the different measurements have values which all fall within a range having a size of between 4 and 25 nm, preferably between 5 and 20 nm.
9. The glass tube element according to any one of the preceding claims,
wherein 360 measurements are carried out each having a different azimuth angle selected from the integer values between, and inclusive of, zero and 359 degrees.
10. The glass tube element according to any one of the preceding claims,
wherein each measurement is carried out for positions having the same height and/or the same radius within the cylindrical coordinate system.
11. The glass tube element according to any one of the preceding claims,
wherein the glass tube element has a length of between 0.5 and 5 m, preferably of between 0.7 and 3 m, more preferably of between 1 and 2 m, even more preferably between 1.2 and 1.8 m and most preferably of 1.5 m.
12. The glass tube element according to any one of the preceding claims,
wherein the maximal outer diameter is between 1 and 100 mm, preferably between 3 and 60 mm, more preferably of between 6 and 45 mm, 8 and 19 mm, 6 and 50 mm or 8 and 30 mm.
13. The glass tube element according to any one of the preceding claims,
wherein the shell has an average thickness of between 0.1 and 5 mm, preferably between 0.2 and 3 mm, more preferably of between 0.3 and 2.5 mm, most preferably between 0.4 and 1.8 mm.
14. The glass tube element according to any one of the preceding claims,
wherein the glass tube element comprises at least in part silicate glass, such as soda line and/or alumosilicate glass, and/or borosilicate glass.
15. The glass tube element according to any one of the preceding claims,
wherein the glass tube element, especially its glass material, has a transition temperature which is higher than 300 degrees C, preferably higher than 500 degrees C, more preferably higher than 520 degrees C, even more preferably higher than 530 degrees C, even more preferably higher than 550 degrees C, and most preferably higher than 600 degrees C and/or lower than 900 degrees C, preferably lower than 800 degrees C, more preferably lower than 700 degrees C, even more preferably lower than 650 degrees C, and most preferably lower than 630 degrees C.
